Ungraded Lab: Model Analysis with TFX Evaluator

Now that you've used TFMA as a standalone library in the previous lab, you will now see how it is used by TFX with its Evaluator component. This component comes after your `Trainer` run and it checks if your trained model meets the minimum required metrics and also compares it with previously generated models.

You will go through a TFX pipeline that prepares and trains the same model architecture you used in the previous lab. As a reminder, this is a binary classifier to be trained on the Census Income dataset. Since you're already familiar with the earlier TFX components, we will just go over them quickly but we've placed notes on where you can modify code if you want to practice or produce a better result.

Let's begin!

Credits: Some of the code and discussions are based on the TensorFlow team's official tutorial.

Setup

Install TFX

```
!pip install -U pip
!pip install -U tfx==1.3

# These are downgraded to work with the packages used by TFX 1.3
# Please do not delete because it will cause import errors in the next cell
!pip install --upgrade tensorflow-estimator==2.6.0
!pip install --upgrade keras==2.6.0
```

```

Note: In Google Colab, you need to restart the runtime at this point to finalize updating the packages you just installed. You can do so by clicking the `Restart Runtime` at the end of the output cell above (after installation), or by selecting `Runtime > Restart Runtime` in the Menu bar. ***Please do not proceed to the next section without restarting.*** *You can also ignore the errors about version incompatibility of some of the bundled packages because we won't be using those in this notebook.*

Imports

```
import os
import pprint
```

```
import tensorflow as tf
import tensorflow_model_analysis as tfma
from tfx import v1 as tfx

from tfx.orchestration.experimental.interactive.interactive_context import InteractiveCont

tf.get_logger().propagate = False
tf.get_logger().setLevel('ERROR')
pp = pprint.PrettyPrinter()
```

Set up pipeline paths

```
# Location of the pipeline metadata store
_pipeline_root = './pipeline/'

# Directory of the raw data files
_data_root = './data/census'

_data_filepath = os.path.join(_data_root, "data.csv")

# Create the TFX pipeline files directory
!mkdir {_pipeline_root}

# Create the dataset directory
!mkdir -p {_data_root}
```

Download and prepare the dataset

Here, you will download the training split of the Census Income Dataset. This is twice as large as the test dataset you used in the previous lab.

```
# Define filename and URL
TAR_NAME = 'C3_W4_Lab_2_data.tar.gz'
DATA_PATH = f'https://storage.googleapis.com/mlep-public/course_3/week4/{TAR_NAME}'

# Download dataset
!wget -nc {DATA_PATH}

# Extract archive
!tar xvzf {TAR_NAME}

# Delete archive
!rm {TAR_NAME}
```

```

```

TFX Pipeline

Create the InteractiveContext

As usual, you will initialize the pipeline and use a local SQLite file for the metadata store.

```
# Initialize InteractiveContext
context = InteractiveContext(pipeline_root=_pipeline_root)
```

```
WARNING:absl:InteractiveContext metadata_connection_config not provided: using SQLit
```

ExampleGen

You will start by ingesting the data through `CsvExampleGen`. The code below uses the default 2:1 train-eval split (i.e. 33% of the data goes to eval) but feel free to modify if you want. You can review splitting techniques here.

```
# Run CsvExampleGen
example_gen = tfx.components.CsvExampleGen(input_base=_data_root)
context.run(example_gen)
```

```
WARNING:apache_beam.runners.interactive.interactive_environment:Dependencies requi
WARNING:root:Make sure that locally built Python SDK docker image has Python 3.7 i
WARNING:apache_beam.io.tfrecordio:Couldn't find python-snappy so the implementatic
```

▼**ExecutionResult** at 0x7fda09433650

.component.inputs	{}
.component.outputs	**['examples']** ▶**Channel** of type **'Examples'** (1 artifact) at 0x7fd9850bbd50

```
# Print split names and URI
artifact = example_gen.outputs['examples'].get()[0]
print(artifact.split_names, artifact.uri)
```

```
["train", "eval"] ./pipeline/CsvExampleGen/examples/1
```

StatisticsGen

You will then compute the statistics so it can be used by the next components.

```
# Run StatisticsGen
statistics_gen = tfx.components.StatisticsGen(
    examples=example_gen.outputs['examples'])
context.run(statistics_gen)
```

```
WARNING:root:Make sure that locally built Python SDK docker image has Python 3.7 int
```

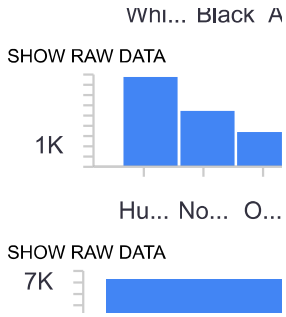
	10.8k	0%	2	Male	7,232	4.66



SchemaGen

You can then infer the dataset schema with SchemaGen. This will be used to validate incoming data to ensure that it is formatted correctly.

```
# Run SchemaGen
schema_gen = tfx.components.SchemaGen(
    statistics=statistics_gen.outputs['statistics'])
context.run(schema_gen)
```

▼ExecutionResult at 0x7fd983ac4590

.execution_id	3
.component	**▶SchemaGen** at 0x7fd9839537d0
.component.inputs	**['statistics'] ▶Channel** of type **'ExampleStatistics'** (1 artifact) at 0x7fd983878250
.component.outputs	**['schema'] ▶Channel** of type **'Schema'** (1 artifact) at 0x7fd983953a50

For simplicity, you will just accept the inferred schema but feel free to modify with the TFDV API if you want.

```
# Visualize the inferred Schema
context.show(schema_gen.outputs['schema'])
```

Artifact at ./pipeline/SchemaGen/schema/3

Feature name	Type	Presence	Valency	Domain
'education'	STRING	required		'education'
'marital-status'	STRING	required		'marital-status'
'native-country'	STRING	required		'native-country'
'occupation'	STRING	required		'occupation'
'race'	STRING	required		'race'
'relationship'	STRING	required		'relationship'
'sex'	STRING	required		'sex'

'fnlwgt'	INT	required		-
'hours-per-week'	INT	required		-
'label'	INT	required		-

```
/usr/local/lib/python3.7/dist-packages/tensorflow_data_validation/utils/display_ut
  pd.set_option('max_colwidth', -1)
```

Domain	Values
	'10th', '11th', '12th', '1st-4th', '5th-6th', '7th-8th', '9th', 'Assoc-acdm', 'Assoc-voc',

ExampleValidator

Next, run `ExampleValidator` to check if there are anomalies in the data.

```
# Run ExampleValidator
example_validator = tfx.components.ExampleValidator(
    statistics=statistics_gen.outputs['statistics'],
    schema=schema_gen.outputs['schema'])
context.run(example_validator)
```

▼ **ExecutionResult** at 0x7fd9839761d0

.execution_id	4
.component	▶ **ExampleValidator** at 0x7fd983072e50

If you just used the inferred schema, then there should not be any anomalies detected. If you modified the schema, then there might be some results here and you can again use TFDV to modify or relax constraints as needed.

In actual deployments, this component will also help you understand how your data evolves over time and identify data errors. For example, the first batches of data that you get from your users might conform to the schema but it might not be the case after several months. This component will detect that and let you know that your model might need to be updated.

```
# Check results
context.show(example_validator.outputs['anomalies'])
```

Artifact at ./pipeline/ExampleValidator/anomalies/4

'train' split:

```
/usr/local/lib/python3.7/dist-packages/tensorflow_data_validation/utils/display_ut
  pd.set_option('max_colwidth', -1)
```

No anomalies found.

'eval' split:

No anomalies found.

Transform

Now you will perform feature engineering on the training data. As shown when you previewed the CSV earlier, the data is still in raw format and cannot be consumed by the model just yet. The transform code in the following cells will take care of scaling your numeric features and one-hot encoding your categorical variables.

Note: If you're running this exercise for the first time, we advise that you leave the transformation code as is. After you've gone through the entire notebook, then you can modify these for practice and see what results you get. Just make sure that your model builder code in the `Trainer` component will also reflect those changes if needed. For example, removing a feature here should also remove an input layer for that feature in the model.

```
# Set the constants module filename
_census_constants_module_file = 'census_constants.py'
```

```
%%writefile {_census_constants_module_file}
```

```
# Features with string data types that will be converted to indices
VOCAB_FEATURE_DICT = {
    'education': 16, 'marital-status': 7, 'occupation': 15, 'race': 5,
    'relationship': 6, 'workclass': 9, 'sex': 2, 'native-country': 42
}

# Numerical features that are marked as continuous
NUMERIC_FEATURE_KEYS = ['fnlwgt', 'education-num', 'capital-gain', 'capital-loss', 'hours-

# Feature that can be grouped into buckets
BUCKET_FEATURE_DICT = {'age': 4}

        }
      }
    }
```

As you already know, the `Transform` component not only outputs the transformed examples but also the transformation graph. This should be used on all inputs when your model is deployed to ensure that it is transformed the same way as your training data. Else, it can produce training-serving skew which leads to noisy predictions.

The `Transform` component stores related files in its `transform_graph` output and it would be good to quickly review its contents before we move on to the next component. As shown below, the URI of this output points to a directory containing three subdirectories.

```
# Get URI and list subdirectories
graph_uri = transform.outputs['transform_graph'].get()[0].uri
os.listdir(graph_uri)
```

```
['transform_fn', 'metadata', 'transformed_metadata']
```

- The `transformed_metadata` subdirectory contains the schema of the preprocessed data.
- The `transform_fn` subdirectory contains the actual preprocessing graph.
- The `metadata` subdirectory contains the schema of the original data.

Trainer

Next, you will now build the model to make your predictions. As mentioned earlier, this is a binary classifier where the label is 1 if a person earns more than 50k USD and 0 if less than or equal. The model used here uses the wide and deep model as reference but feel free to modify after you've completed the exercise. Also for simplicity, the hyperparameters (e.g. number of hidden units) have been hardcoded but feel free to use a `Tuner` component as you did in Week 1 if you want to get some practice.

As a reminder, it is best to start from `run_fn()` when you're reviewing the module file below. The `Trainer` component looks for that function first. All other functions defined in the module are just utility functions for `run_fn()`.

Another thing you will notice below is the `_get_serve_tf_examples_fn()` function. This is tied to the `serving_default` signature which makes it possible for you to just pass in raw features when the model is served for inference. You have seen this in action in the previous lab. This is done by decorating the enclosing function, `serve_tf_examples_fn()`, with tf.function. This indicates that the computation will be done by first tracing a Tensorflow graph. You will notice that this function uses `model.tft_layer` which comes from `transform_graph` output. Now when you call the `.get_concrete_function()` method on this tf.function in `run_fn()`, you are creating the graph that will be used in later computations. This graph is used whenever you pass in an `examples` argument pointing to a Tensor with `tf.string` dtype. That matches the format of the serialized batches of data you used in the previous lab.

▼**ExecutionResult** at 0x7fd98fd5e290

.execution_id	6
.component	▶**Trainer** at 0x7fd982a91e90
.component.inputs	**['examples']** ▶**Channel** of type **'Examples'** (1 artifact) at 0x7fd983931390
	['transform_graph'] ▶**Channel** of type **'TransformGraph'** (1

Let's review the outputs of this component. The `model` output points to the model output itself.

```
# Get `model` output of the component
model_artifact_dir = trainer.outputs['model'].get()[0].uri
```

```
# List top-level directory
pp.pprint(os.listdir(model_artifact_dir))

# Get model directory
model_dir = os.path.join(model_artifact_dir, 'Format-Serving')

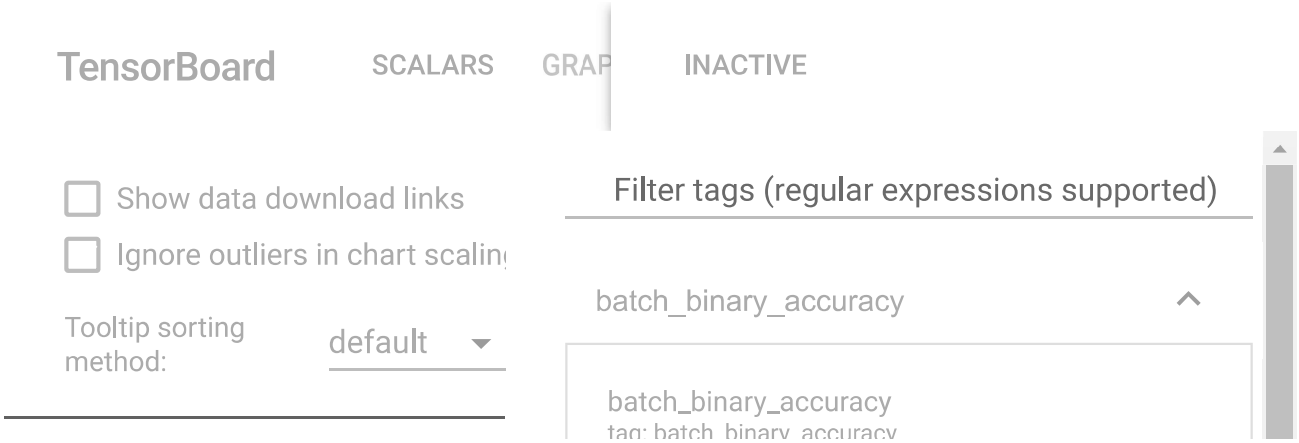
# List subdirectories
pp.pprint(os.listdir(model_dir))
```

```
['Format-Serving']
['keras_metadata.pb', 'assets', 'saved_model.pb', 'variables']
```

The `model_run` output acts as the working directory and can be used to output non-model related output (e.g., TensorBoard logs).

```
# Get `model_run` output URI
model_run_artifact_dir = trainer.outputs['model_run'].get()[0].uri

# Load results to Tensorboard
%load_ext tensorboard
%tensorboard --logdir {model_run_artifact_dir}
```



Evaluator

The `Evaluator` component computes model performance metrics over the evaluation set using the TensorFlow Model Analysis library. The `Evaluator` can also optionally validate that a newly trained model is better than the previous model. This is useful in a production pipeline setting where you may automatically train and validate a model every day.

There's a few steps needed to setup this component and you will do it in the next cells.

Define EvalConfig

First, you will define the `EvalConfig` message as you did in the previous lab. You can also set thresholds so you can compare subsequent models to it. The module below should look familiar. One minor difference is you don't have to define the candidate and baseline model names in the `model_specs`. That is automatically detected.

TOGGLE ALL RUNS

```
import tensorflow_model_analysis as tfma
from google.protobuf import text_format

eval_config = text_format.Parse("""
  ## Model information
  model_specs {
    # This assumes a serving model with signature 'serving_default'.
    signature_name: "serving_default",
    label_key: "label"
  }

  ## Post training metric information
  metrics_specs {
    metrics { class_name: "ExampleCount" }
    metrics {
      class_name: "BinaryAccuracy"
      threshold {
        # Ensure that metric is always > 0.5
        value_threshold {
          lower_bound { value: 0.5 }
        }
        # Ensure that metric does not drop by more than a small epsilon
```

```
          # e.g. (candidate - baseline) > -1e-10 or candidate > baseline - 1e-10
          change_threshold {
            direction: HIGHER_IS_BETTER
            absolute { value: -1e-10 }
          }
        }
      }
      metrics { class_name: "BinaryCrossentropy" }
      metrics { class_name: "AUC" }
      metrics { class_name: "AUCPrecisionRecall" }
      metrics { class_name: "Precision" }
      metrics { class_name: "Recall" }
      metrics { class_name: "MeanLabel" }
      metrics { class_name: "MeanPrediction" }
      metrics { class_name: "Calibration" }
      metrics { class_name: "CalibrationPlot" }
      metrics { class_name: "ConfusionMatrixPlot" }
      # ... add additional metrics and plots ...
    }

    ## Slicing information
    slicing_specs {}  # overall slice
    slicing_specs {
      feature_keys: ["race"]
    }
    slicing_specs {
      feature_keys: ["sex"]
    }
  """, tfma.EvalConfig())
```

Resolve latest blessed model

If you remember in the last lab, you were able to validate a candidate model against a baseline by modifying the `EvalConfig` and `EvalSharedModel` definitions. That is also possible using the `Evaluator` component and you will see how it is done in this section.

First thing to note is that the `Evaluator` marks a model as `BLESSED` if it meets the metrics thresholds you set in the eval config module. You can load the latest blessed model by using the `LatestBlessedModelStrategy` with the Resolver component. This component takes care of finding the latest blessed model for you so you don't have to remember it manually. The syntax is shown below.

```
# Setup the Resolver node to find the latest blessed model
model_resolver = tfx.dsl.Resolver(
      strategy_class=tfx.dsl.experimental.LatestBlessedModelStrategy,
      model=tfx.dsl.Channel(type=tfx.types.standard_artifacts.Model),
      model_blessing=tfx.dsl.Channel(
          type=tfx.types.standard_artifacts.ModelBlessing)).with_id(
              'latest_blessed_model_resolver')
```

```
# Run the Resolver node
context.run(model_resolver)
```

▼**ExecutionResult** at 0x7fd97ddc9ad0

.execution_id	7	
.component	<tfx.dsl.components.common.resolver.Resolver object at 0x7fd97ddc9cd0>	
.component.inputs	**['model']**	▶**Channel** of type **'Model'** (0 artifacts) at 0x7fd97ddc9950
	['model_blessing']	▶**Channel** of type **'ModelBlessing'** (0 artifacts) at 0x7fd97ddc9a90
.component.outputs	**['model']**	▶**Channel** of type **'Model'** (0 artifacts) at

As expected, the search yielded 0 artifacts because you haven't evaluated any models yet. You will run this component again in later parts of this notebook and you will see a different result.

```
# Load Resolver outputs
model_resolver.outputs['model']
```

▼**Channel** of type **'Model'** (0 artifacts) at 0x7fd97dd084d0

.type_name Model
._artifacts []

Run the Evaluator component

With the `EvalConfig` defined and code to load the latest blessed model available, you can proceed to run the `Evaluator` component.

You will notice that two models are passed into the component. The `Trainer` output will serve as the candidate model while the output of the `Resolver` will be the baseline model. While you can indeed run the `Evaluator` without comparing two models, it would likely be required in production environments so it's best to include it. Since the `Resolver` doesn't have any results yet, the `Evaluator` will just mark the candidate model as `BLESSED` in this run.

Aside from the eval config and models (i.e. Trainer and Resolver output), you will also pass in the *raw* examples from `ExampleGen`. By default, the component will look for the `eval` split of these examples and since you've defined the serving signature, these will be transformed internally before feeding to the model inputs.

```
# Setup and run the Evaluator component
evaluator = tfx.components.Evaluator(
    examples=example_gen.outputs['examples'],
    model=trainer.outputs['model'],
    baseline_model=model_resolver.outputs['model'],
    eval_config=eval_config)
context.run(evaluator, enable_cache=False)
```

```
WARNING:root:Make sure that locally built Python SDK docker image has Python 3.7 int
```

▼**ExecutionResult** at 0x7fd97a6e4150

.execution_id	8	
.component	▶**Evaluator** at 0x7fd97caac550	
.component.inputs	**['examples']**	▶**Channel** of type **'Examples'** (1 artifact) at 0x7fd9850bbd50
	['model']	▶**Channel** of type **'Model'** (1 artifact) at 0x7fd982a91b10
	['baseline_model']	▶**Channel** of type **'Model'** (0 artifacts) at 0x7fd97dd084d0
.component.outputs	**['evaluation']**	▶**Channel** of type **'ModelEvaluation'** (1 artifact) at

Now let's examine the output artifacts of `Evaluator`.

```
# Print component output keys
evaluator.outputs.keys()
```

```
dict_keys(['evaluation', 'blessing'])
```

The `blessing` output simply states if the candidate model was blessed. The artifact URI will have a `BLESSED` or `NOT_BLESSED` file depending on the result. As mentioned earlier, this first run will pass the evaluation because there is no baseline model yet.

```
# Get `Evaluator` blessing output URI
blessing_uri = evaluator.outputs['blessing'].get()[0].uri

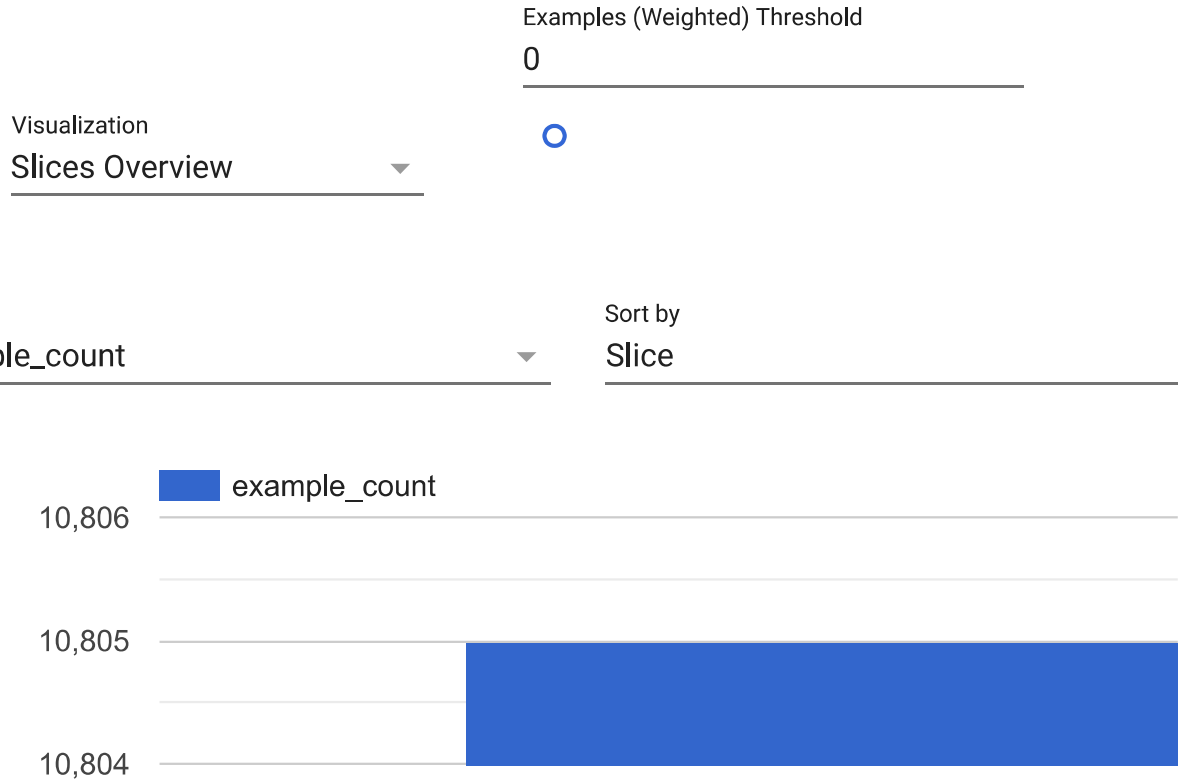
# List files under URI
os.listdir(blessing_uri)
```

```
['BLESSED']
```

The `evaluation` output, on the other hand, contains the evaluation logs and can be used to visualize the global metrics on the entire evaluation set.

```
# Visualize the evaluation results
context.show(evaluator.outputs['evaluation'])
```

Artifact at ./pipeline/Evaluator/evaluation/8



To see the individual slices, you will need to import TFMA and use the commands you learned in the previous lab.

```
import tensorflow_model_analysis as tfma

# Get the TFMA output result path and load the result.
PATH_TO_RESULT = evaluator.outputs['evaluation'].get()[0].uri
tfma_result = tfma.load_eval_result(PATH_TO_RESULT)

# Show data sliced along feature column trip_start_hour.
tfma.view.render_slicing_metrics(
    tfma_result, slicing_column='sex')
```

You can also use TFMA to load the validation results as before by specifying the output URI of the evaluation output. This would be more useful if your model was not blessed because you can see the metric failure prompts. Try to simulate this later by training with fewer epochs (or raising the threshold) and see the results you get here.

sex:Female 0.89790 0.57930

```
# Get `evaluation` output URI
PATH_TO_RESULT = evaluator.outputs['evaluation'].get()[0].uri

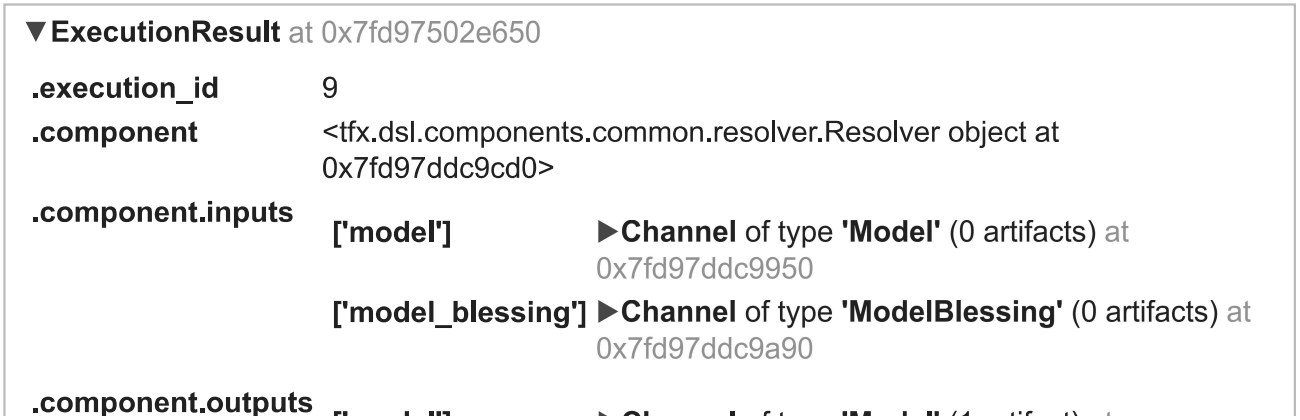
# Print validation result
print(tfma.load_validation_result(PATH_TO_RESULT))
```

```
validation_ok: true
validation_details {
  slicing_details {
    slicing_spec {
    }
    num_matching_slices: 8
  }
}
```

Now that your `Evaluator` has finished running, the `Resolver` component should be able to detect the latest blessed model. Let's run the component again.

```
# Re-run the Resolver component
```

```
context.run(model_resolver)
```



You should now see an artifact in the component outputs. You can also get it programmatically as shown below.

```
# Get path to latest blessed model
model_resolver.outputs['model'].get()[0].uri
```

```
'./pipeline/Trainer/model/6'
```

Comparing two models

Now let's see how `Evaluator` compares two models. You will train the same model with more epochs and this should hopefully result in higher accuracy and overall metrics.

```
# Setup trainer to train with more epochs
trainer = tfx.components.Trainer(
    module_file=os.path.abspath(_census_trainer_module_file),
    examples=transform.outputs['transformed_examples'],
    transform_graph=transform.outputs['transform_graph'],
    schema=schema_gen.outputs['schema'],
    train_args=tfx.proto.TrainArgs(num_steps=500),
    eval_args=tfx.proto.EvalArgs(num_steps=200))

# Run trainer
context.run(trainer, enable_cache=False)
```

You will re-run the evaluator but you will specify the latest trainer output as the candidate model. The baseline is automatically found with the Resolver node.

```
# Setup and run the Evaluator component
evaluator = tfx.components.Evaluator(
    examples=example_gen.outputs['examples'],
    model=trainer.outputs['model'],
    baseline_model=model_resolver.outputs['model'],
    eval_config=eval_config)
context.run(evaluator, enable_cache=False)
```

```
WARNING:root:Make sure that locally built Python SDK docker image has Python 3.7 int
```

Depending on the result, the Resolver should reflect the latest blessed model. Since you trained with more epochs, it is most likely that your candidate model will pass the thresholds you set in the eval config. If so, the artifact URI should be different here compared to your earlier runs.

```
# Re-run the resolver
context.run(model_resolver, enable_cache=False)
```
